My Stats Rant

- There's a lot of bad practice in terms of stats in archaeology
- Reliance on outliers, but usually only visually, without doing any formalized outlier analysis
- Lots of uncertainty and error propagation in isotopic analyses (my sub-discipline)
- Decided to completely avoid p-values
- Big fan of the "Johns" - Tukey and Kruschke - so used a Tukey-eque Exploratory Data Analysis and "New Statistics" approach

'..."statistically significant"—don't say it and don't use it.'

Wasserstein, Schirm, and Lazar (2019)

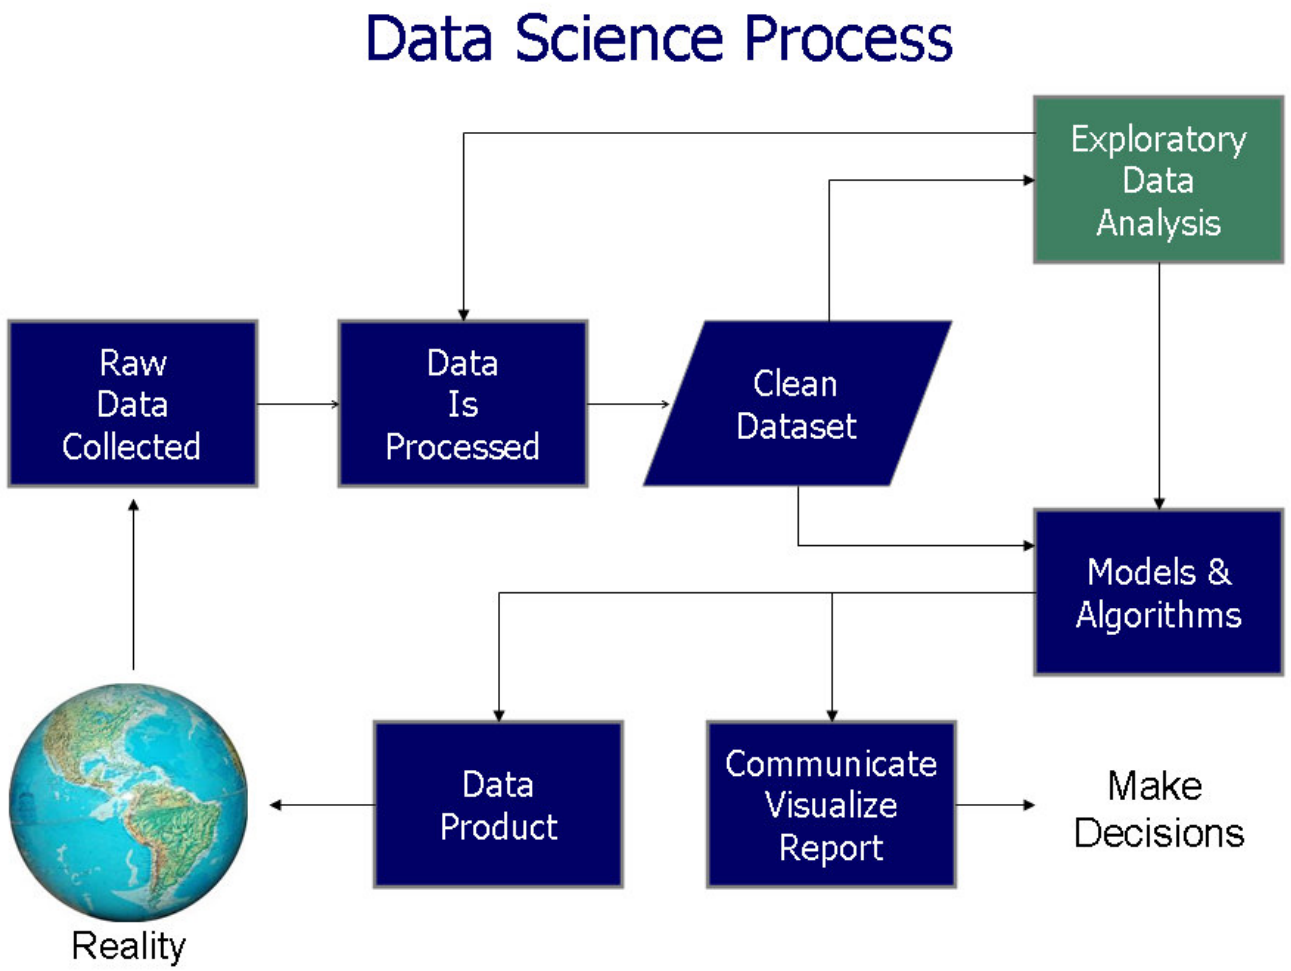
John W. Tukey and Exploratory Data Analysis (EDA)



"actively incisive rather than passively descriptive, with real emphasis on the discovery of the unexpected" (Tukey, 1977)

Arose in reaction to an over-emphasis/reliance on NHST (aka confirmatory data analysis) – you need to understand and see your data to be able to suggest what hypotheses to test (many statisticians now abhor HST full stop)

This doesn't mean we don't start with theories/ideas/hypotheses to test – but that shouldn't be our statistical starting point

Case Study: The Fish Event Horizon & Meta-analysis

'Dark Age Economics' revisited: the English fish bone evidence AD 600-1600

James H. Barrett,[1] Alison M. Locker[2] & Callum M. Roberts[3]

When did the market economy come to Europe? Fish might seem an unlikely commodity to throw light on the matter, but the authors use fish bones from English sites to offer a vivid account of the rise and rise of the market as a factor in European development from the late tenth century.

Keywords: England, Europe, medieval, Dark Age, fish, trade, market

Introduction

Twenty-two years ago – when Richard Hodges (1982) published his influential monograph *Dark Age Economics* – two observations regarding early medieval economy seemed clear. Firstly, the transition from exchange of high-value prestige goods to low-value staples (and thus, in his view, from gift-exchange to market trade, from proto-urban settlements to true towns and from substantivist to formalist economics) was central to an understanding of European socio-economic change. Secondly, although complex and uneven in detail, this transition could be dated to the tenth and eleventh centuries. Hodges was, of course, not alone in these observations. The growth of trade and urbanism had long played an important role in defining the Viking Age (e.g. Arbmann 1939; Jankuhn 1956; Blindheim 1975; Bencard 1981). Moreover, *Dark Age Economics* was one contribution to a movement within medieval archaeology that was heavily influenced by economic and neo-evolutionary anthropology (e.g. Grierson 1959; Callmer 1977; Randsborg 1980; Jankuhn 1982). It thus found an audience primed for either reception or resistance (Astill 1985; Sawyer 1989).

Since then, however, archaeology has confirmed the existence of early (particularly eighth century) antecedents to many of North-western Europe's first towns, and of other early markets without urban populations (Cowie & Whytehead 1988; Hill *et al.* 1990; Ulriksen 1994; Kemp 1996; Feveile & Jensen 2000; Gardiner *et al.* 2001; see contributions in Hansen & Wickham 2000; Hill & Cowie 2001; Prestell & Ulmschneider 2003). Concurrently, accessible surveys of the relevant historical evidence have emphasised the existence and scale of commercial transactions – including the exchange of basic staple goods – in Carolingian times (e.g. Verhulst 1995; 2002). Wider paradigm shifts within archaeology have also peripheralised the neo-evolutionary basis of Hodges' original argument (Gosden 1999:88-105; Gerrard 2003:172, 217-231). It is thus not surprising to find that interpretations have

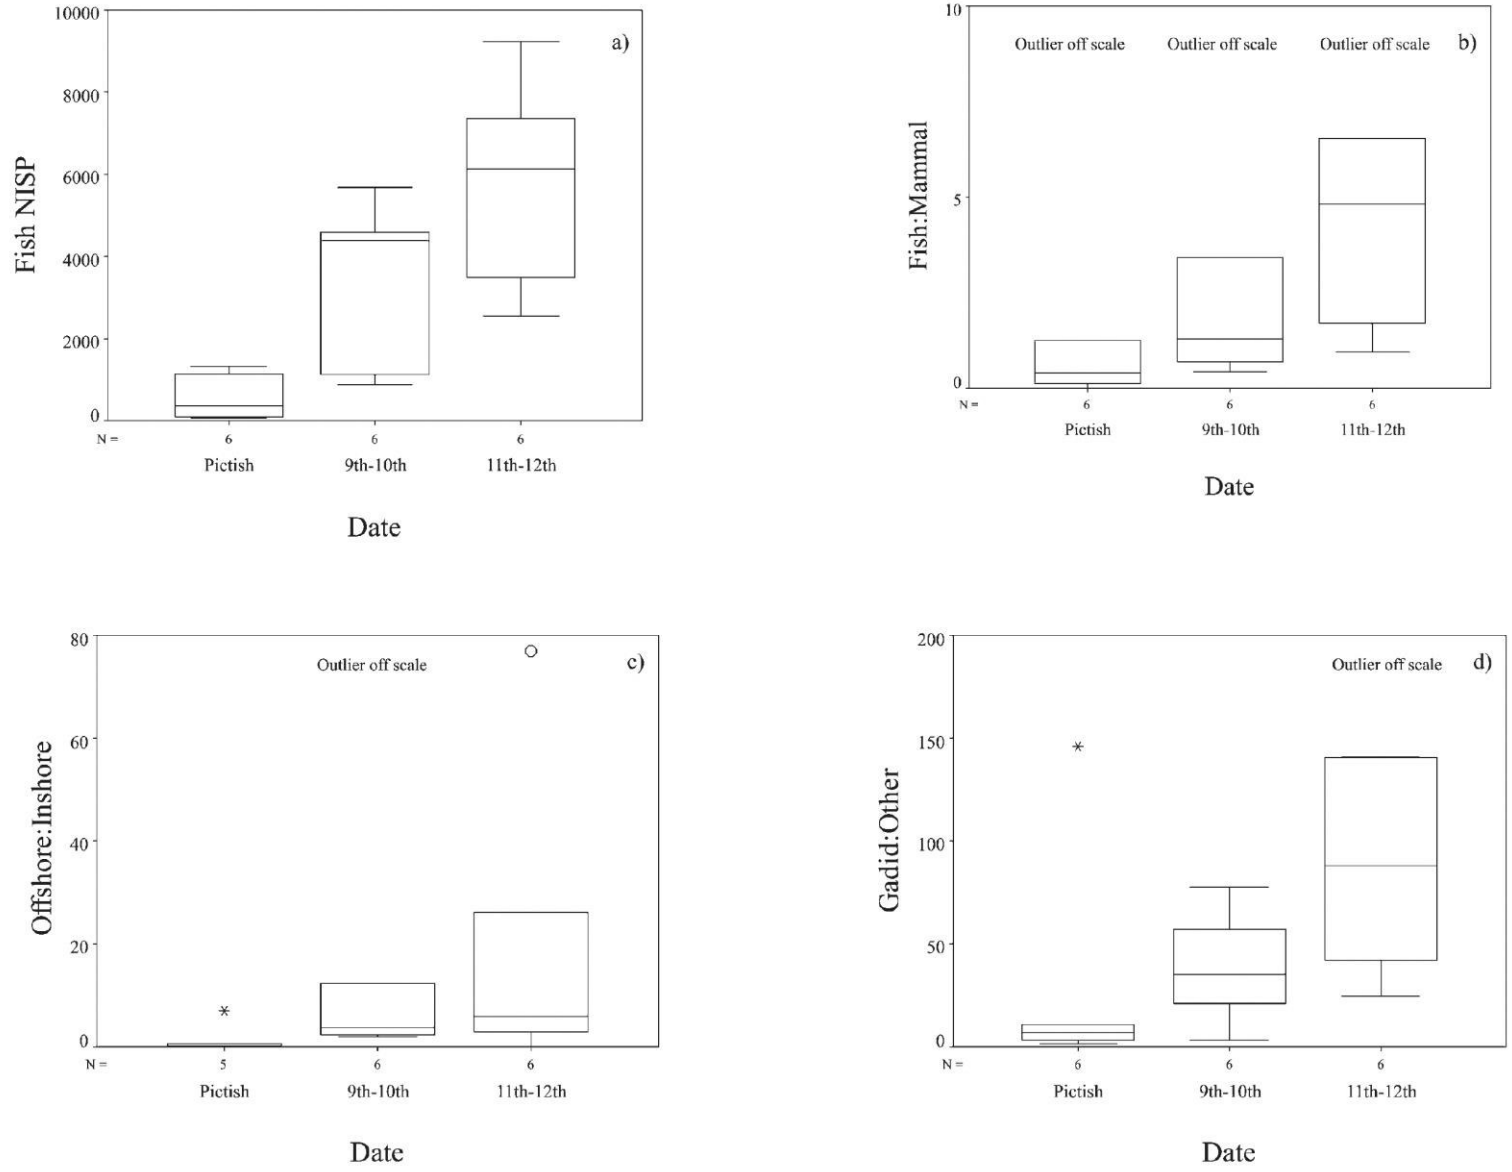

Figure 4. Boxplots showing increases in the intensity of fishing, and the importance of cod and related species, in northern Scotland during both the ninth/tenth and eleventh/twelfth centuries AD. The preceding 'Pictish' period covers approximately the fourth to eighth centuries. (a) The number of fish bones recovered. (b) The ratio of fish bone to mammal bone. (c) The ratio of inshore to offshore taxa – based on a comparison of ling (Molva molva) and Torsk (Brosme brosme) to rocklings (Ciliata or Gaidropsarus species), wrasse (Labridae) and cottids (Cottidae). (d) The ratio of cod family to all other fish. The data are based on NISP figures and have been taken from Barrett and Oltmann (1998); Barrett et al. (1999; 2001) and references therein.

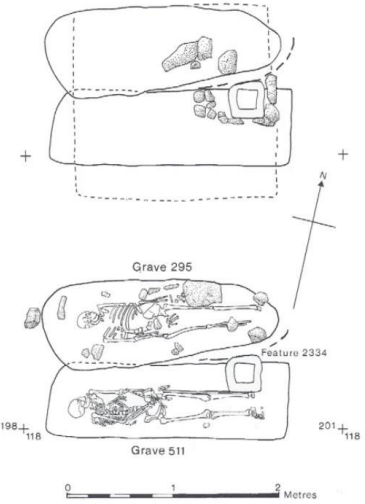
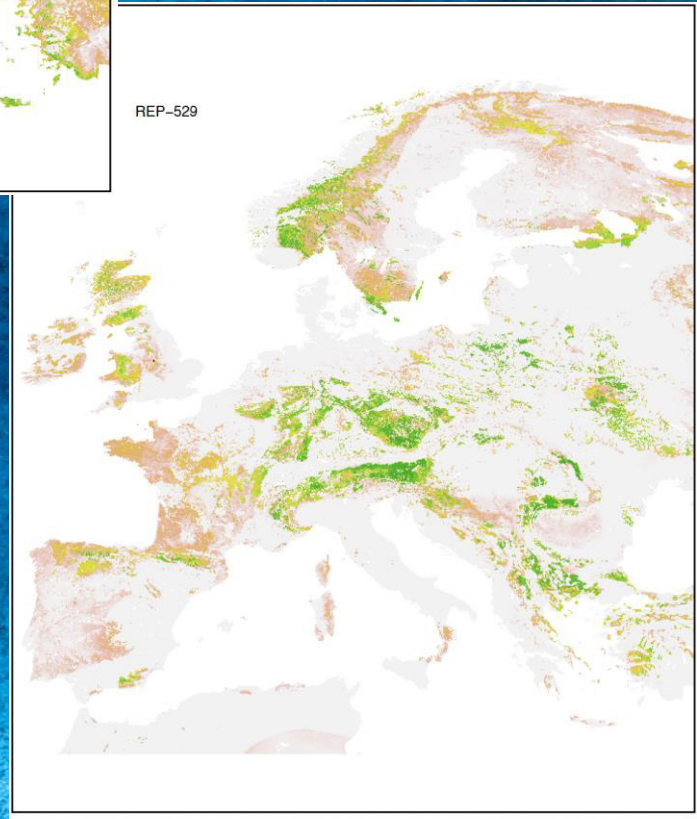
New radiocarbon dates from Repton have confirmed that the charnel dead are consistent with a 9th-century date, meaning that the human remains could have come from the Viking Great Army. [Image: Cat Jarman]



Recent aDNA analysis of G5ll and G295 has suggested that the two men may be father and son. [Image: © Martin Biddle/ Judith Dobie]



The Fish Event Horizon in Early Medieval Britain

- Clearly there in the zooarchaeological record, especially associated with urban and high-status sites
- The earliest pre-Viking "fishy" outliers are Scandinavian migrants
- In the lead up to the 11th century few coastal or riverine communities are consuming fish in isotopically visible amounts
- Seems to be a foodway predominantly associated with Scandinavian communities in the Danelaw in England
- To a lesser extent also clear in Christian communities – tricky to disentangle with Danelaw and local baseline impact in many cases (e.g. East Anglia)
- Scotland has a more striking shift – especially on Orkney (Barrett et al. 2001; Barrett 2003; Barrett and Richards 2004)
- Well established (isotopically) in human diets by the later medieval period (Müldner 2016; Rose 2021)
- Evidence for community assimilation (change from 'fishy' childhood to more terrestrial adulthood)

Stats/Data viz take aways

- Think about the questions you're asking or the story you want to tell and analyze/visualize accordingly
- So much more you can say without p-values using EDA
- Consider the shape/distribution of the data and not just dive into look for outliers or compare means

DATA ANALYSIS

ANDREW MCLEAN &
FANG JACKSON-YANG

OUTLINE

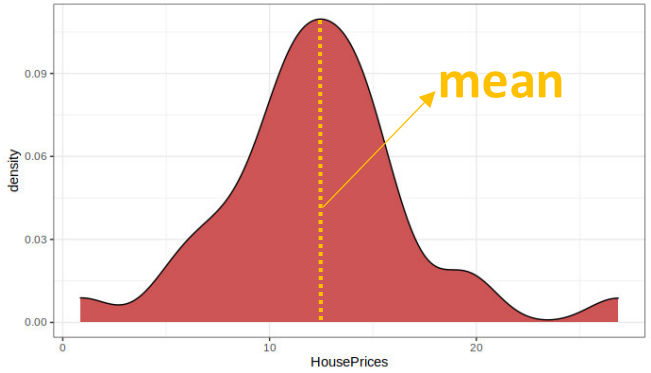
- Descriptive Statistics
- Inferential Statistics: Linear Regression
- Inferential Statistics: Null Hypothesis Testing

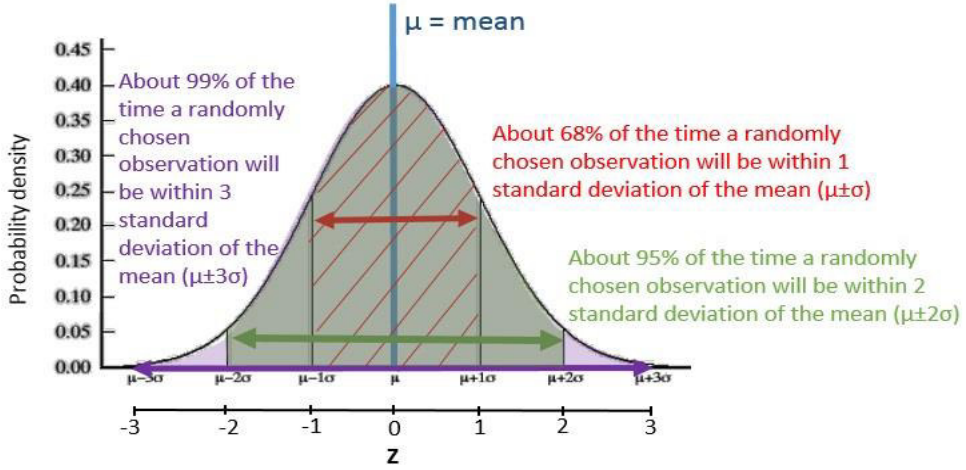
STATISTICS

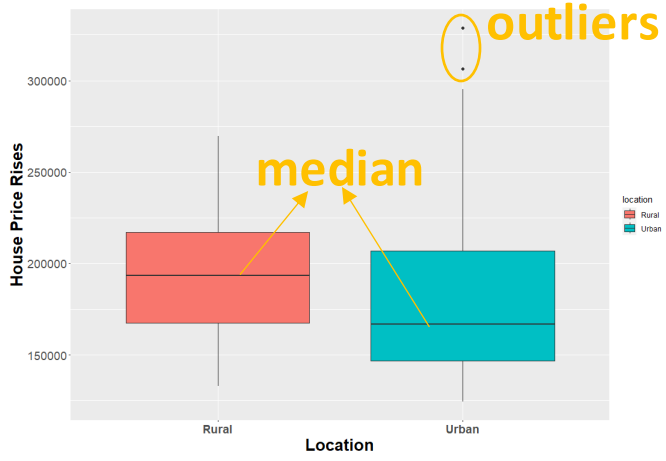
- Two main types: Descriptive & Inferential.
- Descriptive statistics are used to summarise data.
- Inferential statistics are used to make inferences (and predictions) about the world based on the observed data.

DESCRIPTIVE STATISTICS

- Distribution & central tendency
- Mean, median, standard deviation (sd)





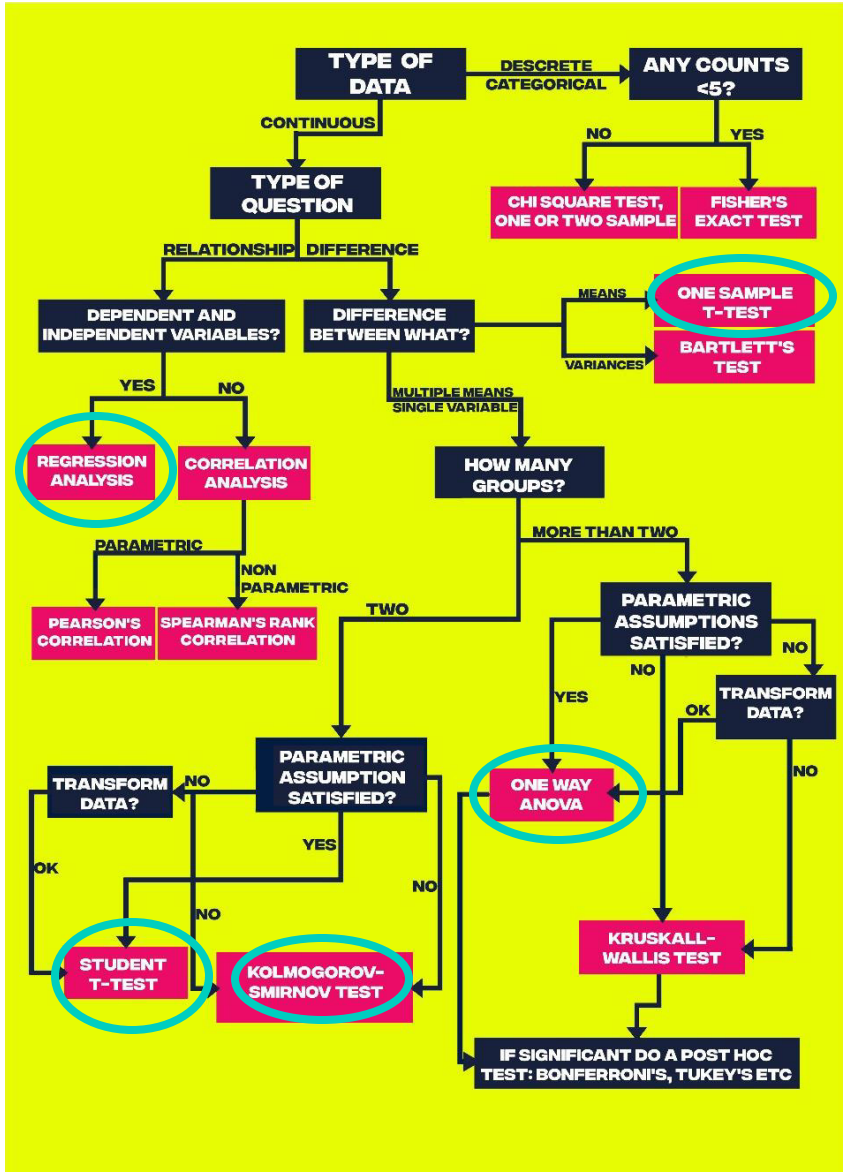


Resource: http://dev1.ed-projects.nyu.edu/statistics/normal-distribution/

INFERENTIAL STATISTICS

LOTS OF CHOICES TO BE MADE

- Nature of the research question
- Nature of the data
- Objectives



LINEAR REGRESSION

- **Linear Model:** $Y \sim \beta_0 + \beta_1 X + \varepsilon$ (in R: **lm(Y ~ X, data)**)

- **Model Interpretation**

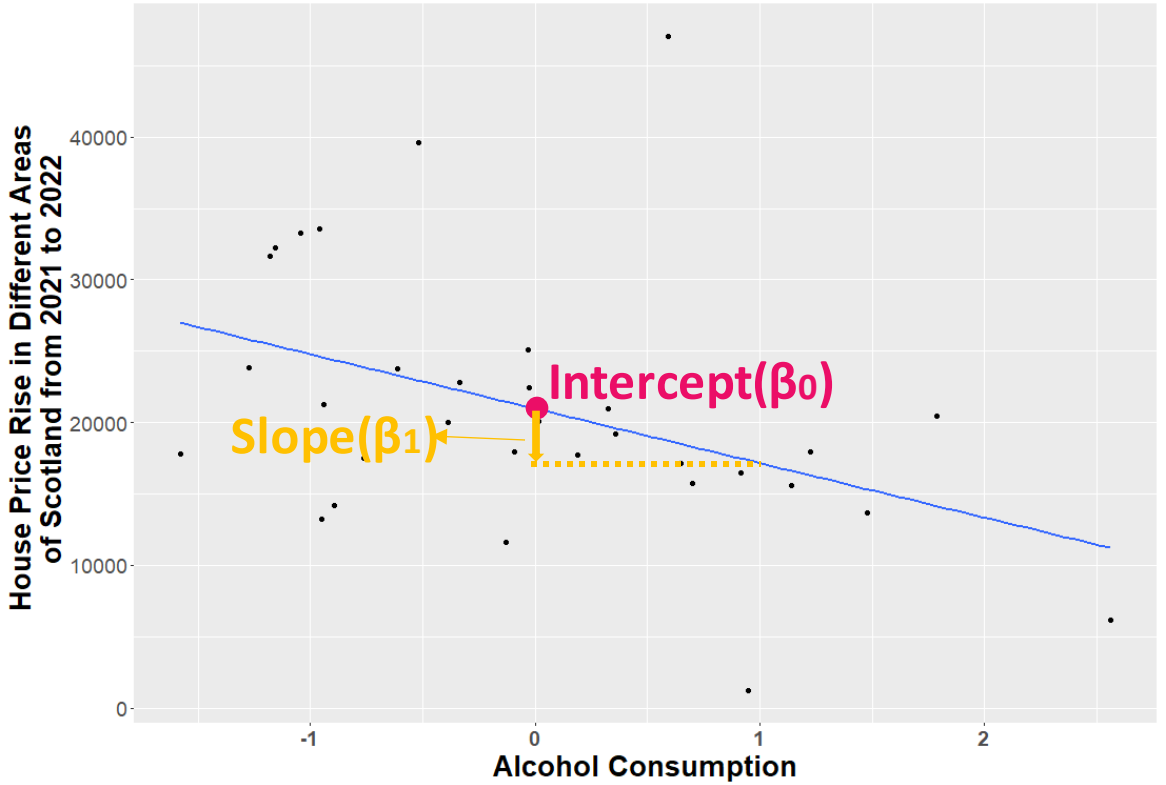
- **Intercept**: the expected value of y when x is 0.
- **Slope**: the rate of change (number of units by which y increases as x increases by 1 unit).

- **Model evaluation**

- How much variance does the model account for?
- How much does the model fit improve over chance?

- **Model comparison**

- Does model fit improve if we add an additional independent variable? (in R: **anova(**m1, m2**)**)



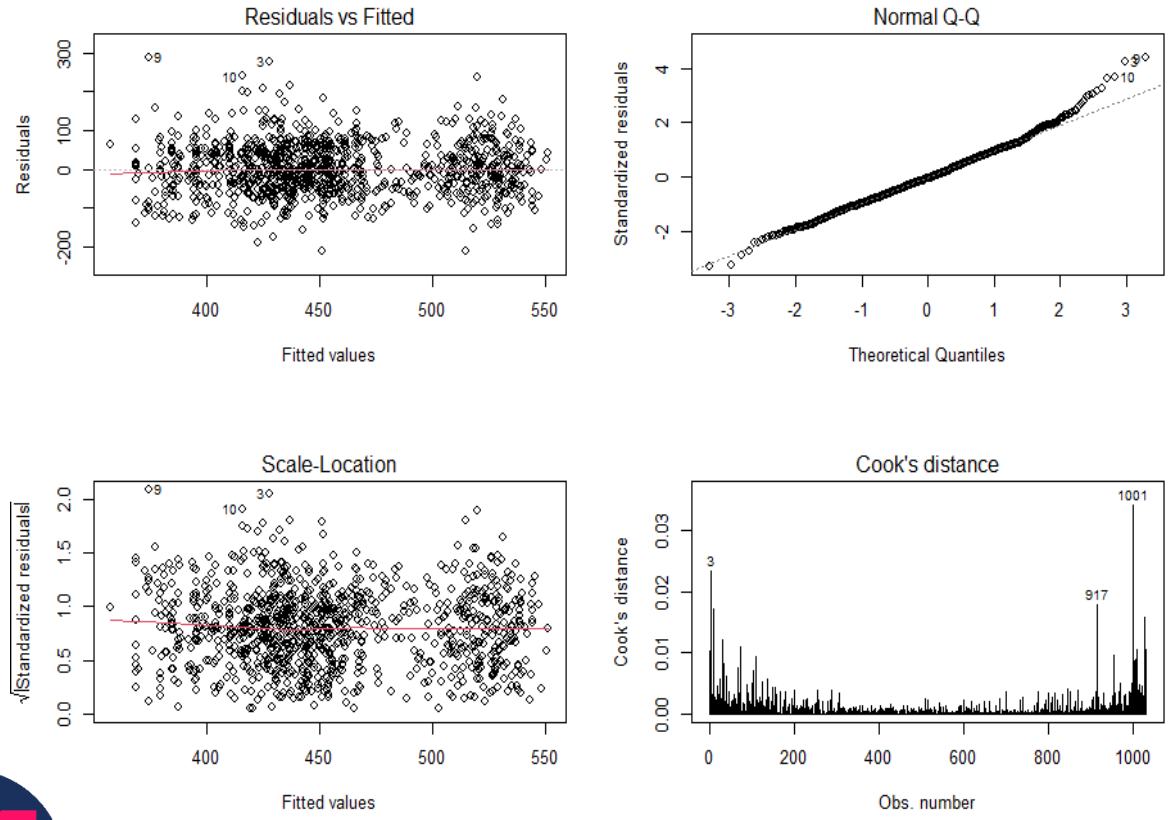
ASSUMPTION CHECK

FOR LINEAR REGRESSION MODELS:

- Linearity of relationships
- Independence of residuals
- Normality of residuals
- Equal variances for residuals
- Ideally no collinearity & no outliers

FOR T-TESTs:

- Normally distributed data

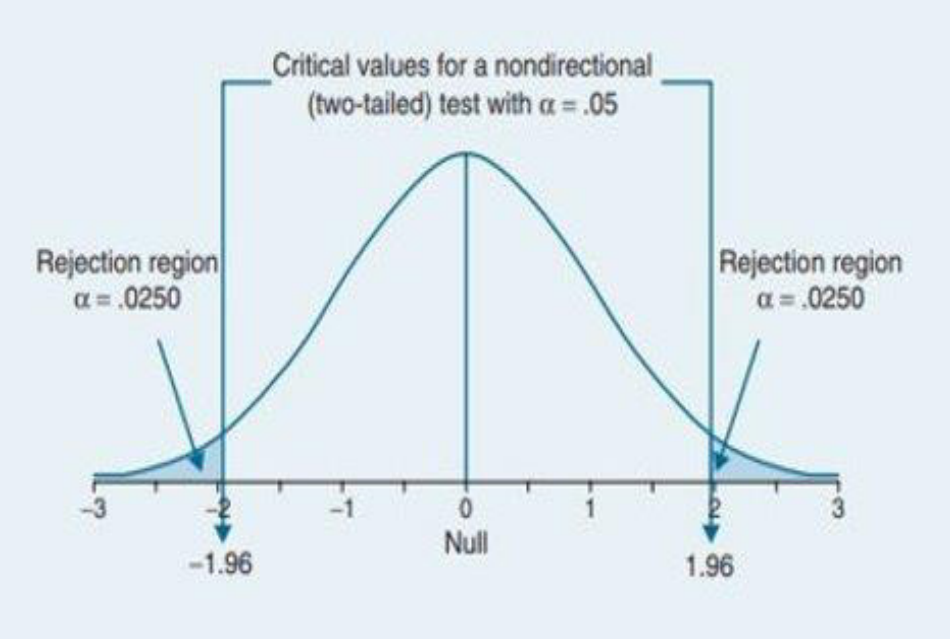


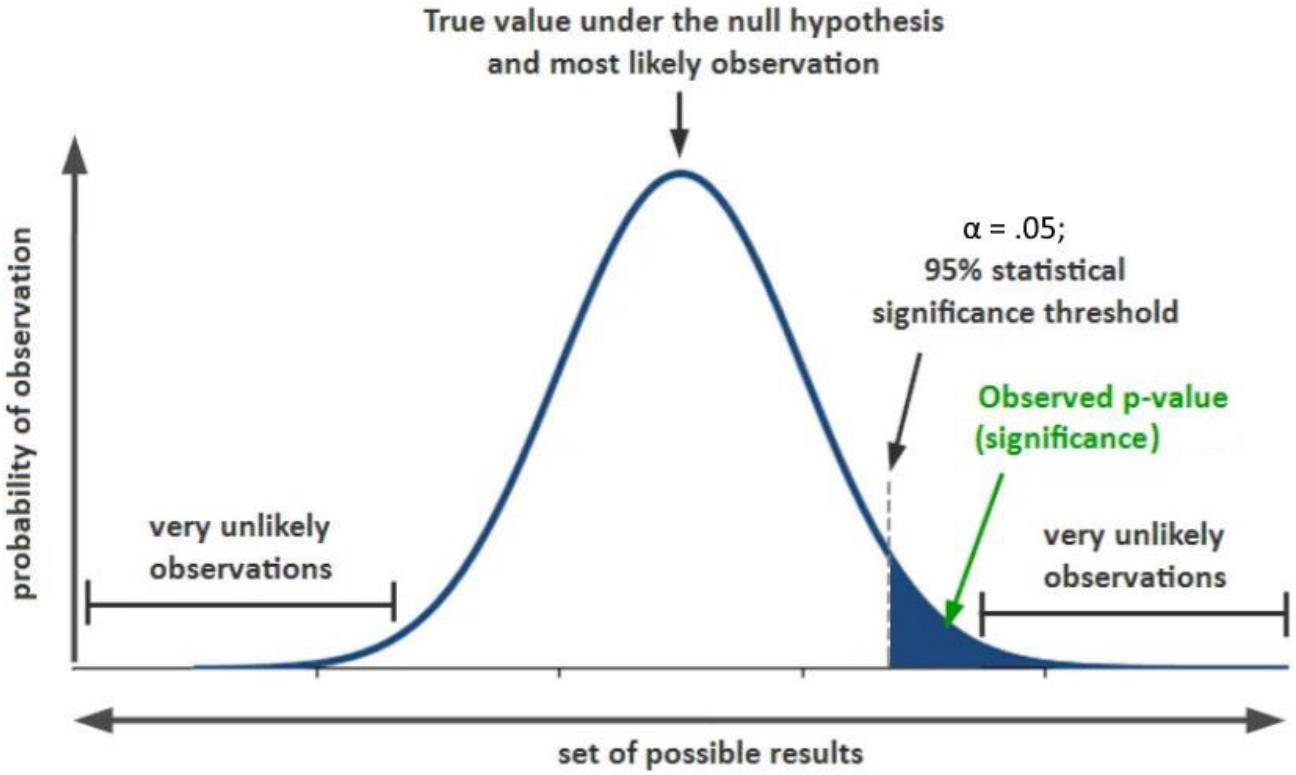
NULL HYPOTHESIS TESTING (NHT)

- Hypotheses are claims researchers make about the world based on some data.
- NHT is a formal method for validating hypotheses, by comparing a theoretically non-null hypothesis (H_1) with a null hypothesis (H_0).
  - H_1: House price rises associated with alcohol consumption.
  - H_0: House price rises not associated with alcohol consumption.
- The goal is to accept or reject **H0** (not H_1) and then make inferences about H1.
  - H_1: Pandas are black and white.
  - H_0: Some pandas are not.

NULL HYPOTHESIS TESTING (NHT)

- Goal: Reject or accept H_0





Resources: https://medium.com/datadriveninvestor/p-value-t-test-chi-square-test-anova-when-to-use-which-strategy-32907734aa0e; https://www.sagepub.com/sites/default/files/upm-binaries/40007_Chapter8.pdf; https://learningstatisticswithr.com/lsr-0.6.pdf

NULL HYPOTHESIS TESTING (NHT)

- Two types of errors in decision making

		Decision	
		Retain H_0	Reject H_0
H_0 Truth	True	1 - α = probability of correct retention	α (type I error rate)
	False	β (type II error rate)	1 - β = power of the test

Resources: https://medium.com/datadriveninvestor/p-value-t-test-chi-square-test-anova-when-to-use-which-strategy-32907734aa0e; https://www.sagepub.com/sites/default/files/upm-binaries/40007_Chapter8.pdf; https://learningstatisticswithr.com/lsr-0.6.pdf

CLUSTER ANALYSIS
JAMES PAGE

WHAT IS CLUSTER ANALYSIS

- Cluster analysis is a way of dividing objects in a dataset into groups made up of similar characteristics.
- Many different types of cluster analysis. We will only cover a few.
- Have urban and rural local authorities been similarly impacted by the cost of living crisis?

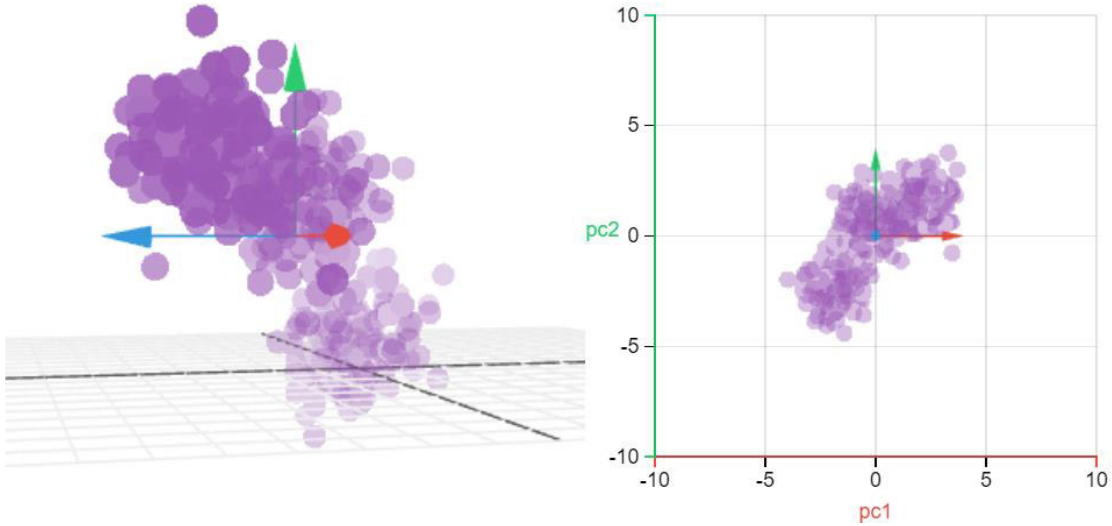
PRINCIPAL COMPONENT ANALYSIS (PCA)

Principal component analysis (PCA) is a technique used to emphasize variation and bring outline patterns in a dataset

When to Apply?

- 3 or more continuous variables
- 1 or more categorical variable (not mandatory)

When there are more than two variables, it can be difficult to isolate underlying patterns in a dataset because it's hard to see through a cloud of data.



HOW IT WORKS

PCA can be used to find out which of our variables cause the most variation in our dataset

- Theoretically, variables with high variation will have a higher chance of creating patterns when plotted.
- These Principal Components (PCs) are ranked.
  - PC1 contains the highest variation.
  - PC2 the second, PC3 the third etc.

HOW IT WORKS

As most variation are captured by PC1 and PC2 so we can use them to replot our sample in two dimensions, discarding the other PCs.

- To do this, PCA generates a new coordinate system in which every point has a new (x,y) value in relation to their distance from the lines for PC1 and PC2.
- The axes don't actually mean anything physical; they're combinations of the original variables.

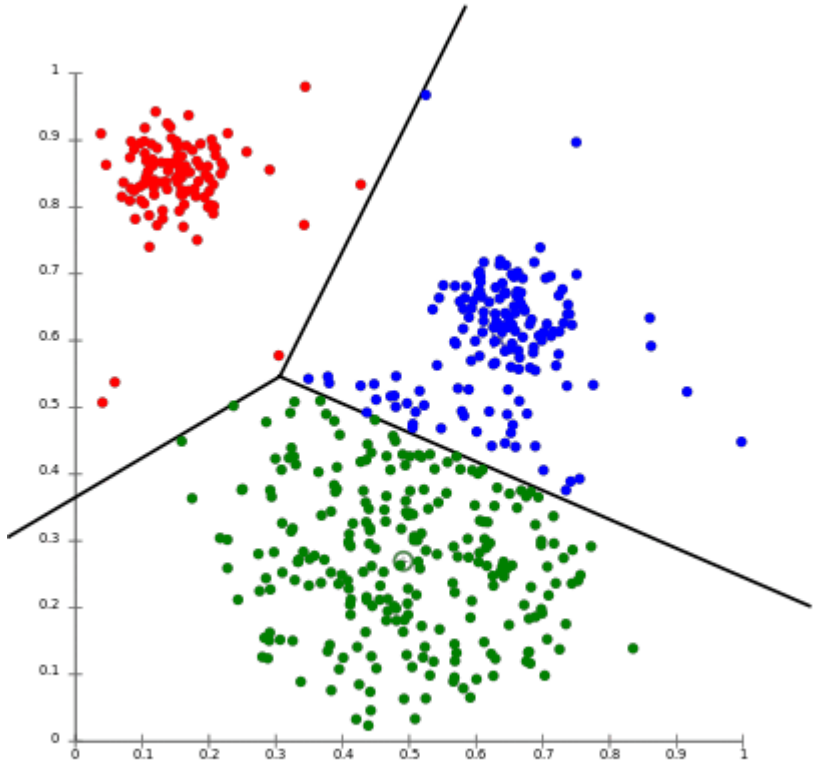
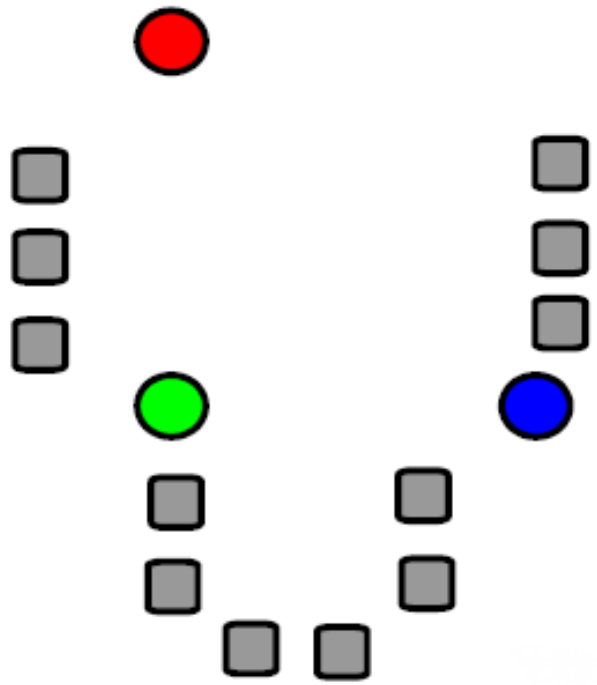
K-MEANS CLUSTERING

- K-means clustering is one of the simplest and popular unsupervised machine learning algorithms.
- The objective of K-means is simple: group similar data points together and discover underlying patterns.
- To achieve this objective, K-means looks for a fixed number (k) of clusters in a dataset.



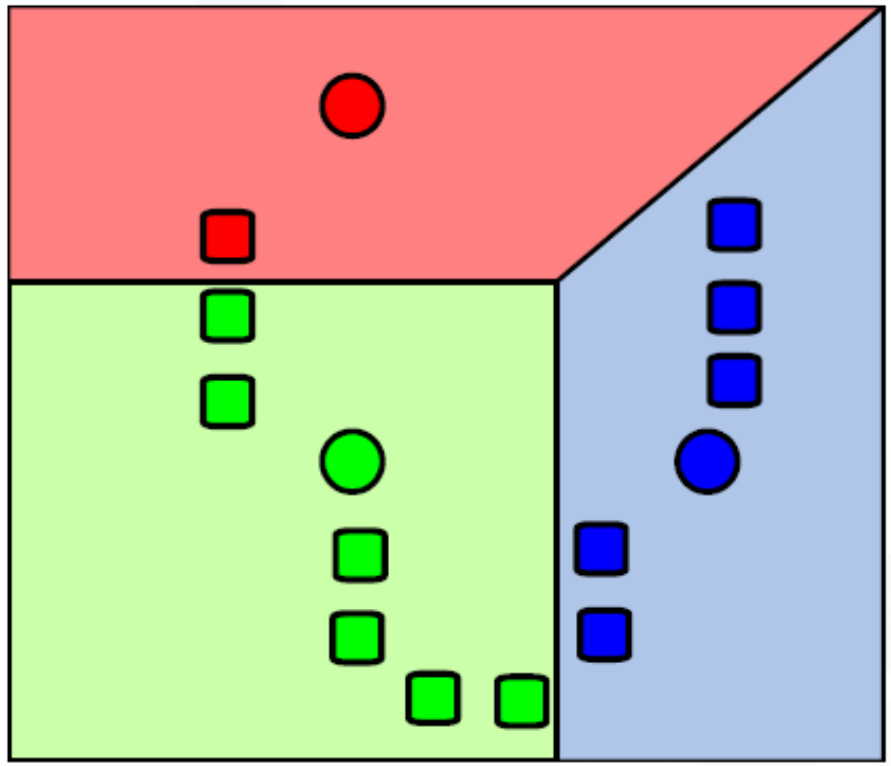
K-MEANS CLUSTERING

- To begin, we define a target number k, which refers to the number of centroids we need in the dataset.
- A centroid is the imaginary or real location representing the centre of the cluster.
- Initially, a point is randomly selected as the centre of each group.



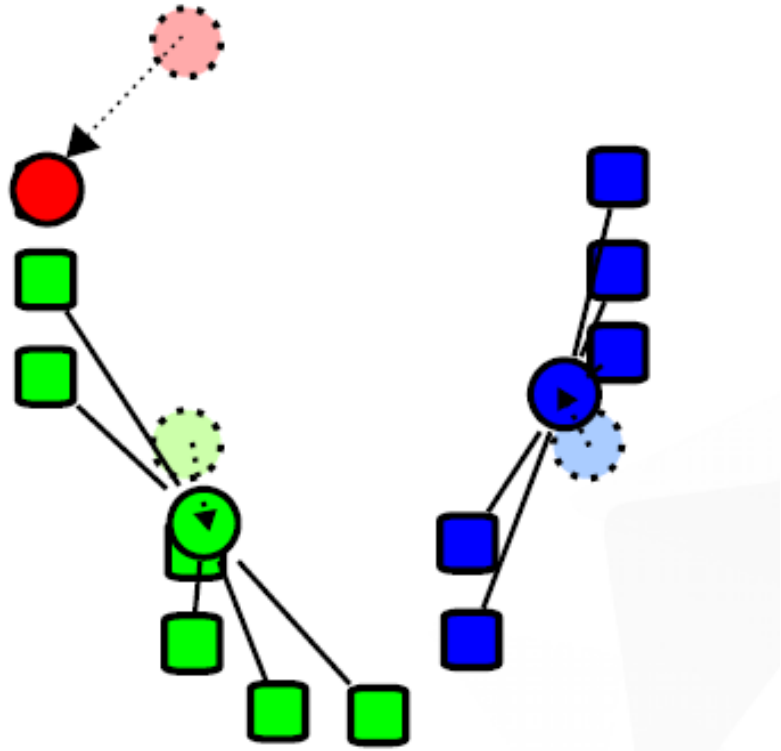
K-MEANS CLUSTERING

- Samples are then split based on Euclidean distance.



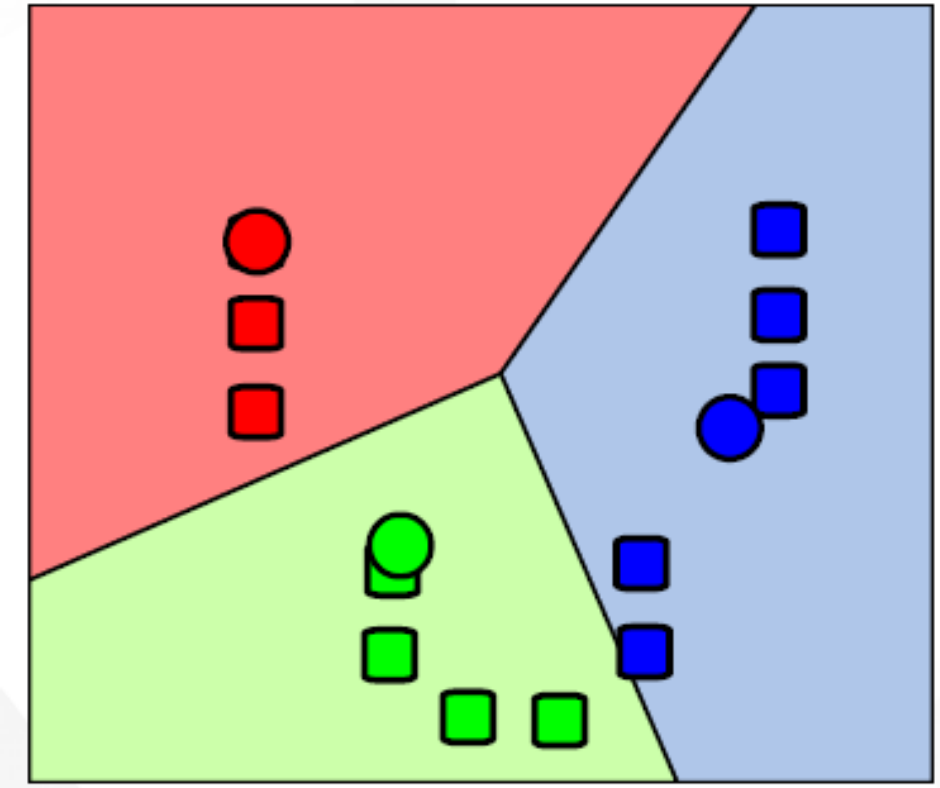
K-MEANS CLUSTERING

- To process the learning data, the K-means algorithm in data mining starts with a first group of randomly selected centroids, which are used as the beginning points for every cluster.
- It then performs iterative (repetitive) calculations to optimize the positions of the centroids.



K-MEANS CLUSTERING

- The sample is then reclassified based on the new centres.
- The algorithm halts creating and optimizing clusters when either:
  - The centroids have stabilized — there is no change in their values because the clustering has been successful.
  - The defined number of iterations has been achieved.



K-MEANS CLUSTERING

- K-means clustering is one of the simplest and popular unsupervised machine learning algorithms.
- However, it does have some drawbacks.
- Its performance is usually not as competitive as those of the other sophisticated clustering techniques because slight variations in the data could lead to high variance.
- Clusters are assumed to be spherical and evenly sized, something which may reduce the accuracy of the results.

Searching for AI's killer app for Humanities research

Professor Melissa Terras

Professor of Digital Cultural Heritage
Director, Edinburgh Centre for Data, Culture & Society
Director of Research, Edinburgh Futures Institute

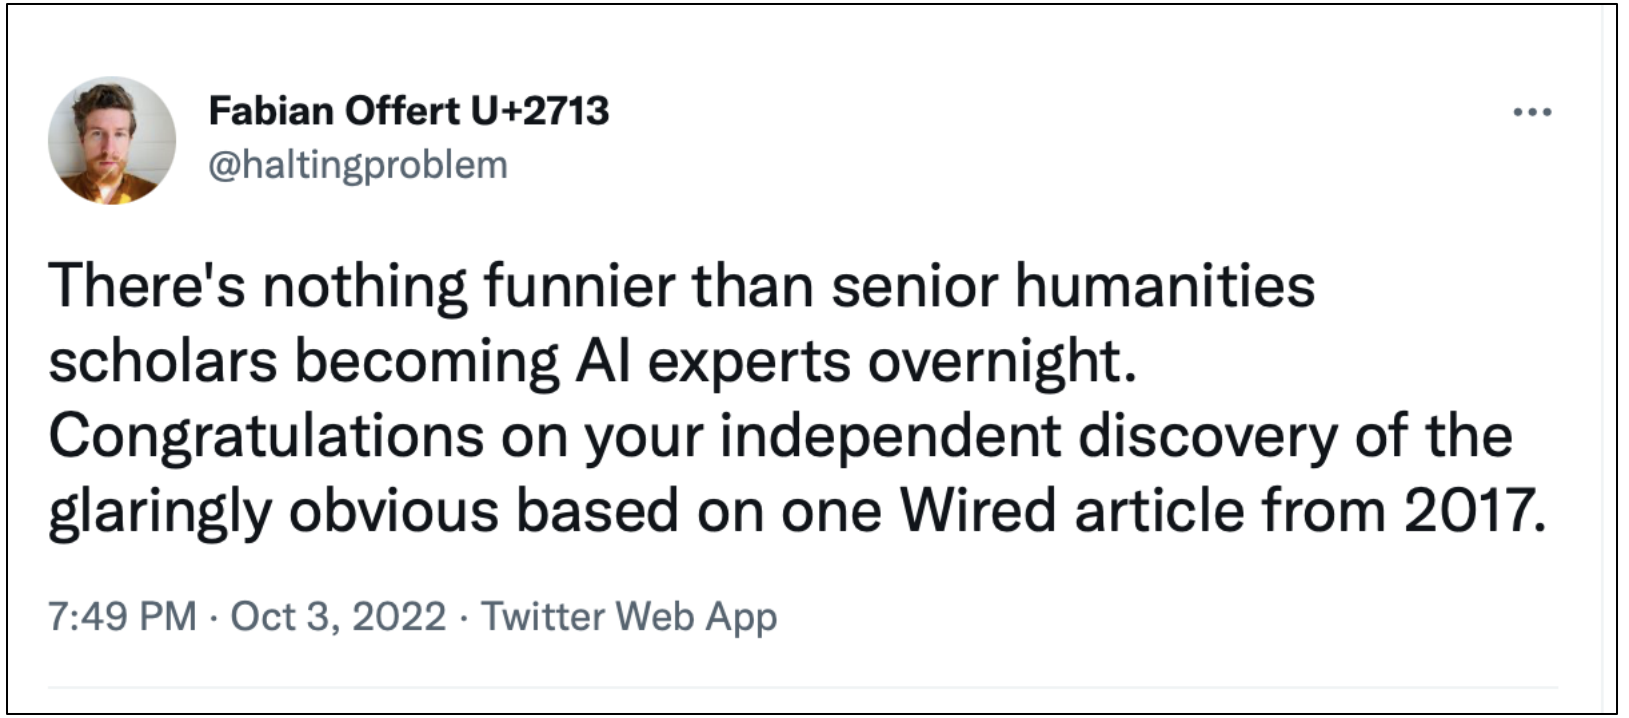
m.terras@ed.ac.uk
@melissaterras

Overview

- (What gives me the right to have an opinion?)
- The long history of Artificial Intelligence (AI) in the Humanities
- But the difficulties for AI for the Humanities
- Speculative Design Process – what would a killer AI App in the Humanities look like?
  - Three AI tools I wished existed to help me with my Humanities research!
- How can we build these type of AI applications in the humanities?
- And why the AI table needs us.

Artificial Intelligence / Humanities

- AI
  - The capacity of computers or other machines to exhibit or simulate intelligent behaviour; the field of study concerned with this. (OED)
- Humanities
  - The branch of learning concerned with human culture; the academic subjects collectively comprising this branch of learning, as history, literature, ancient and modern languages, law, philosophy, art, and music. (OED)



Fabian Offert U+2713
@haltingproblem

There's nothing funnier than senior humanities scholars becoming AI experts overnight. Congratulations on your independent discovery of the glaringly obvious based on one Wired article from 2017.

A Horse That She Believed Scottish Parage has Laughing Life to Special Song Jazz

Prepare to bring you the stirring story of The Concert of Giddi Shane and internationally acclaimed traditional music and returns to the Edinburgh Fringe with a celebration of successful designers and the female burst in the ruin and the silly mother. This is the story of a true story.

Join the music to Granchon's traditional comedy by Decasent Features, the Show Out of the Boy of the Book of on a deceptive new comedy about the works of modern Comedy Central and ghosts with theatre, supporting charity women and desperate top strange cardboard arguments.

The above show blurb was generated by The Bot, using a recurrent neural network on 2,098,140 words of Fringe show listings (2011-2019).

Abstract

The work described in this paper is concerned with the development of microcomputer software to aid the process of academic editing. Editorial procedures are represented as a network of operations that are designed to provide both advice and assistance. To achieve these aims knowledge has been encapsulated in the network so that an editor can interact with the system which is able to act as an aide memoire, an advisor, a production facility and an extending memory. This expert system has been formed from the experience gained in editing the Association for Literary and Linguistic Computing (ALLC) Bulletin.

Why didn't these projects scale…

- Niche
- Specific domain
- Need training
- Need updating/ sustaining
- Effort worth the investment?
- Lack of funding/ opportunities
- Market changes/ approach changes
- "AI Winter"

Nowadays – AI Spring – AI Everywhere

- In our search environments
- In our shopping environments
- In our writing environments
- In our artistic environments
- … Yet where is it designed for purely humanistic research?

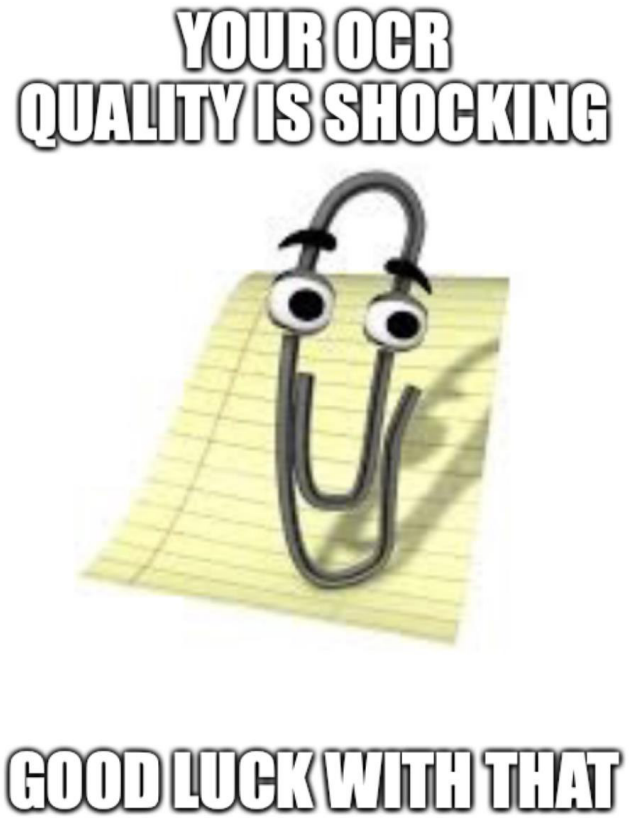
LOOKING FOR AI
TOOLS FOR THE HUMANITIES
NOPE

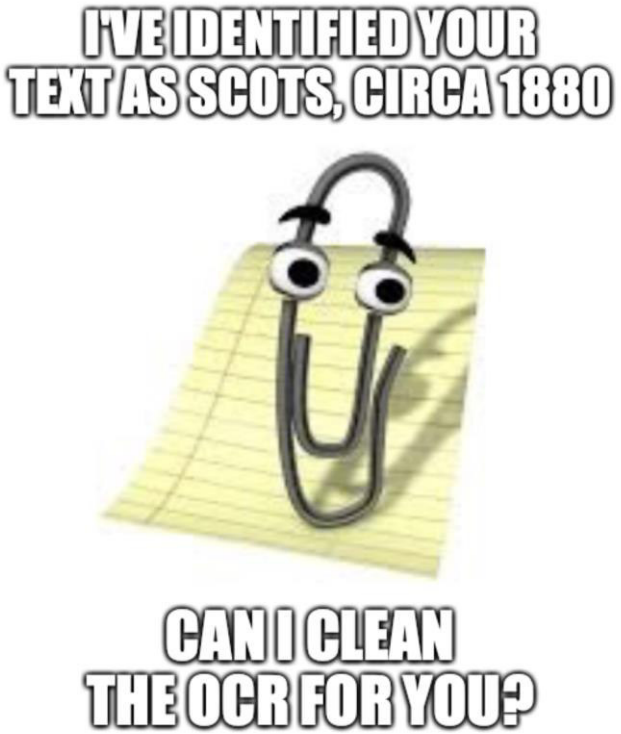
Speculative Design

- “Design futuring approaches, such as speculative design, design fiction and others, seek to (re)envision futures and explore alternatives.”
- Articulate possibilities
- Generate new directions for work
- Analyze own and others work
- Kozubaev, Sandjar, Chris Elsden, Noura Howell, Marie Louise Juul Søndergaard, Nick Merrill, Britta Schulte, and Richmond Y. Wong. "Expanding modes of reflection in design futuring." In *Proceedings of the 2020 CHI Conference on Human Factors in Computing Systems*, pp. 1-15. 2020.
- Three AI tools I wished existed for my Humanities/ DH Research… and what that tells us.

1: OCR Correction

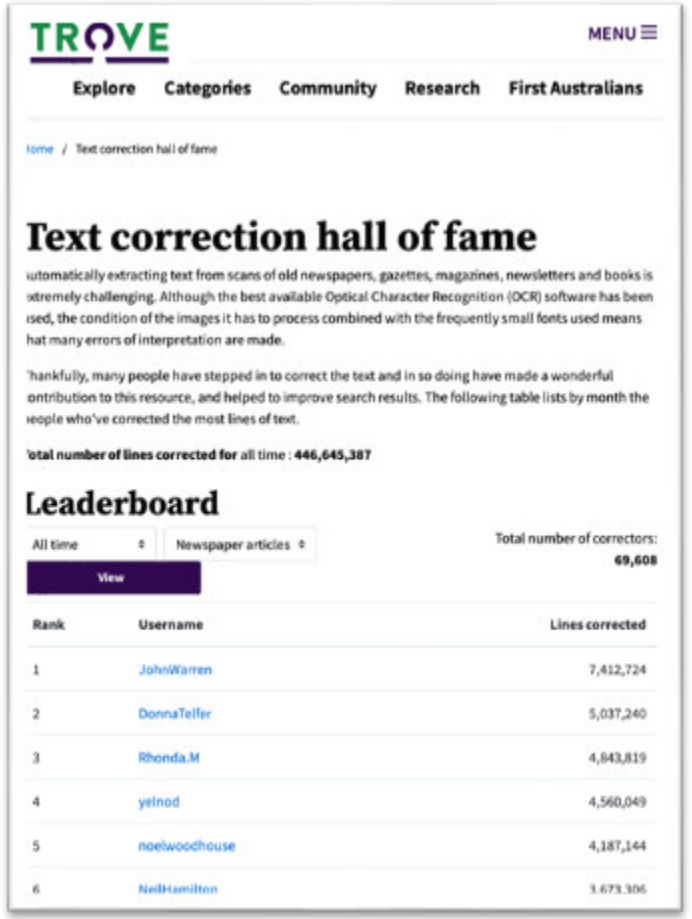


1. An AI system to provide domain specific OCR cleaning



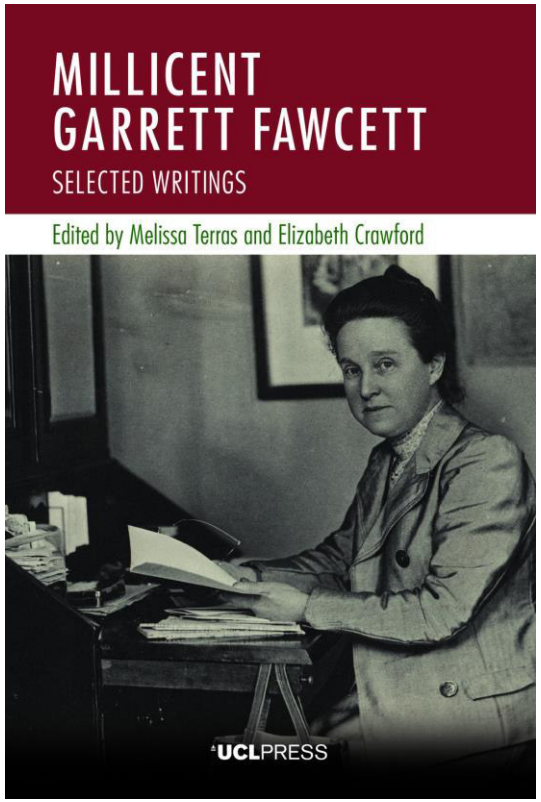
This would require:

- A way to differentiate between checked/cleaned mass OCR and dirty OCR for training
- Getting access to the cleaned OCR/ open licensing
- Building subject level AND local granularity
- Preparing our digitized collections for the robots!
- Access to ML infrastructure
  - Specific LLMs



https://trove.nla.gov.au/landing/community/hallOfFame

2. An AI system to find source quotations across mass digitized systems



"Things won are done; joy's soul lies in the doing"

Troilus and Cressida (1.2.173)

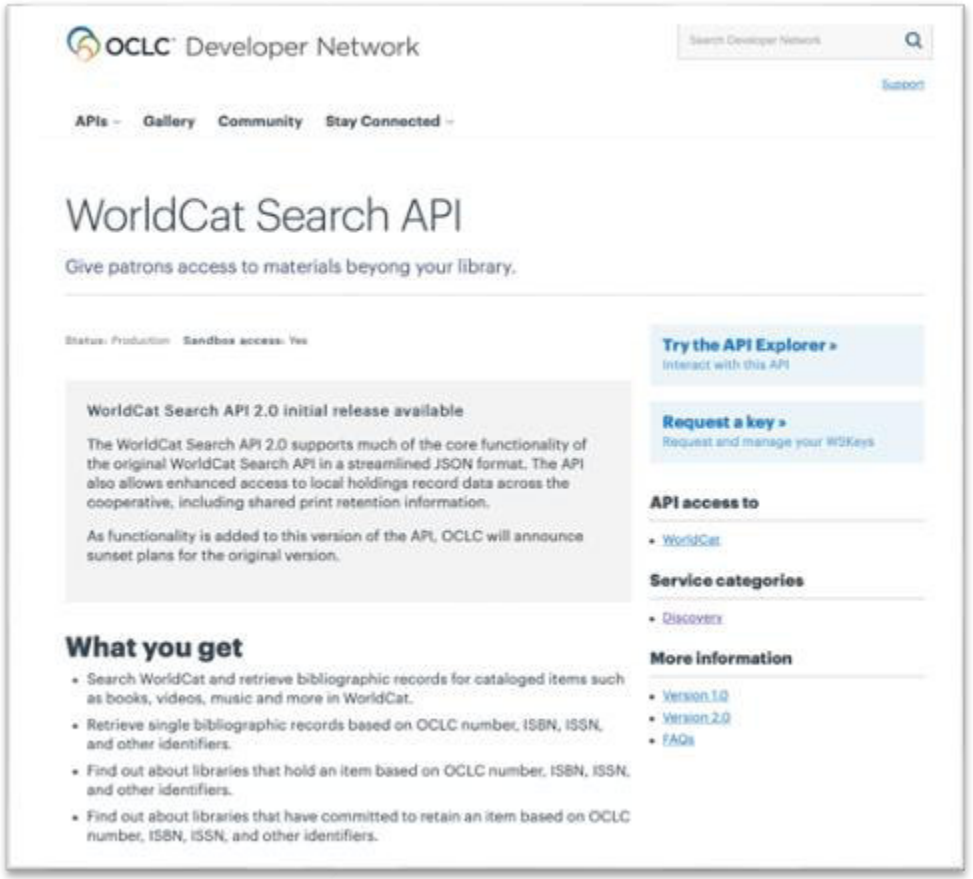
https://discovery.ucl.ac.uk/id/eprint/10149793/1/Millicent-Garret-Fawcett.pdf

This would require

- Cleaning up of OCR! (hello!)
- Federation of mass digitized content
- Agreement on search APIs between major commercial suppliers
- Ability to weight algorithms as you learn a subject's habit (try *The Times*, then *The Evening* News, then *The Scotsman*…)
- Rapid cycling, reviewing, learning, agility, improvement…

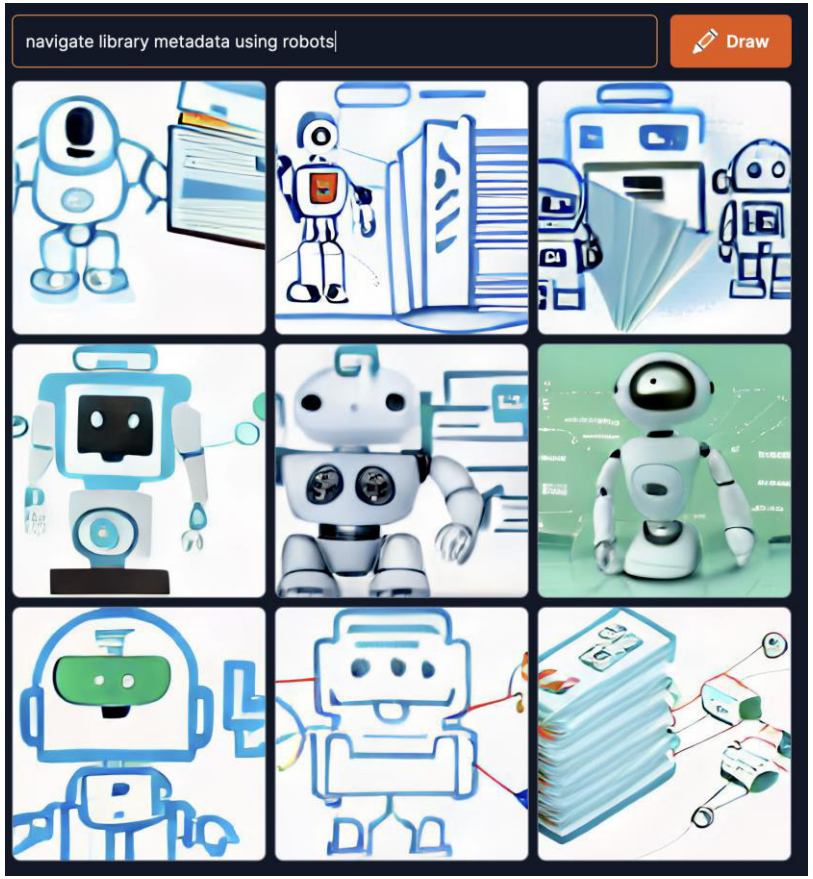
3. An AI system to find me new stuff in library databases!

- Often things you are looking for have same size/ publisher/ keywords
- But different cataloguers
- “Find me anything that may be a suffrage pamphlet”



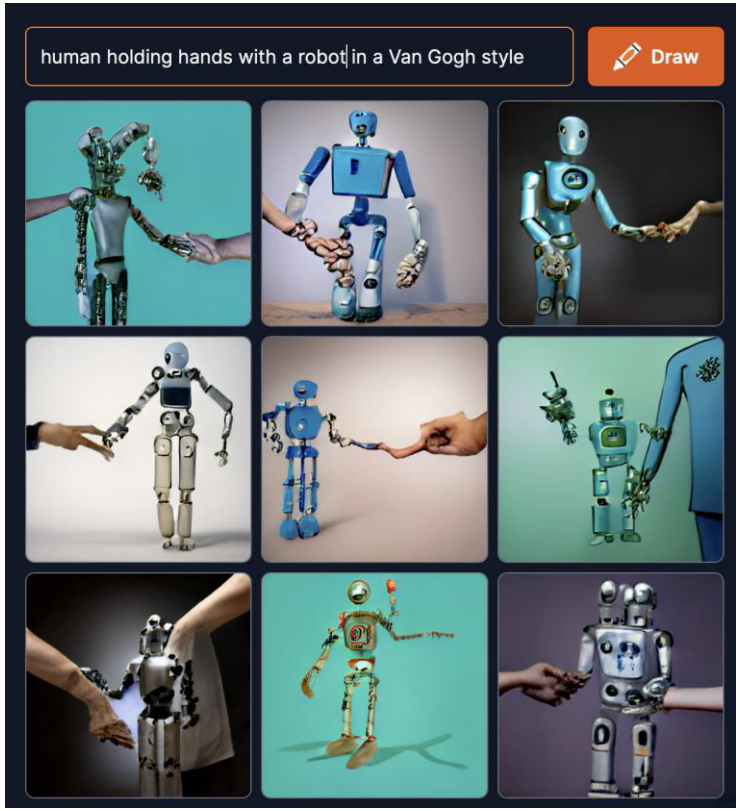
This would require

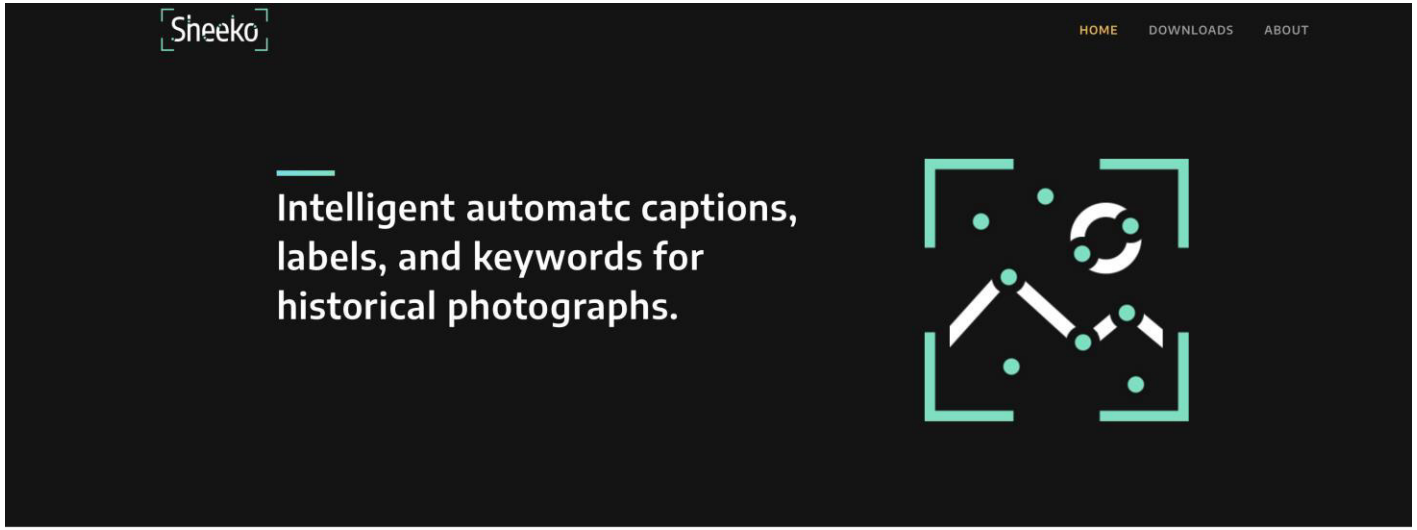
- Cleaning catalogue data
- Access to OCLC API
- Access to Library Metadata
- (which needs to be prepared for & ingested by the robots)
- Clear understanding of search structure, terms, importance
- Tweaking weighting – symbiosis with system
- Way to narrow down searches rapidly – UX challenges



Get AI to do the boring stuff

- (I want to decide what is boring, for my own research question. Let's acknowledge boring is relative)
- What is rote? What can be automated? Is that harder to define in the Humanities?
- Administrative processes?
- Where can we tweak, and control?
- Let computers do things at scale, and *bring things to me* to use my capacity to sort/analyse/synthesise
- We've built it for HTR. Where else?





Automatic Metadata Generation

High-quality metadata is the bedrock of Digital Library systems, as it helps in users discovering the unique content in various collections housed in digital libraries.

Creating metadata is a time-intensive manual process and is done by experts who are trained in metadata schemas, and taxonomies; but the process is a bottleneck in adding content to digital libraries.

Project Sheeko examines the use of machine learning techniques to extract useful information from images that will assist metadata experts.

melissa terras
@melissaterras

This is my biggest fear about where we are with language based generative AI - an absolute crumbling of digital infrastructure that allows you to find anything real - or know what is legit. We'll need some fair trade certification for hand-hewn words, soon...

Anosognosiogenesis @pookleblinky · May 30

Wait til amazon scammers start selling [redacted] AI generated fake books. You look up Stephen King's the Stand and the real one is hidden in a crowd of [redacted]awful 5,000 word regurgitations, etc.

How do we build them?

- Digital Infrastructure isn't cheap.
- No Business Model. Not Revenue generating.
  - Transkribus had over 11m EUR funding before it stood on its own two feet…
- There's only so much voluntary "open science" we can do.
- Lack of joined up thinking re mass-digitized collections: silos
- Need for digitization of *more* content
- Lack of funding for the Arts and Humanities in comparison to science

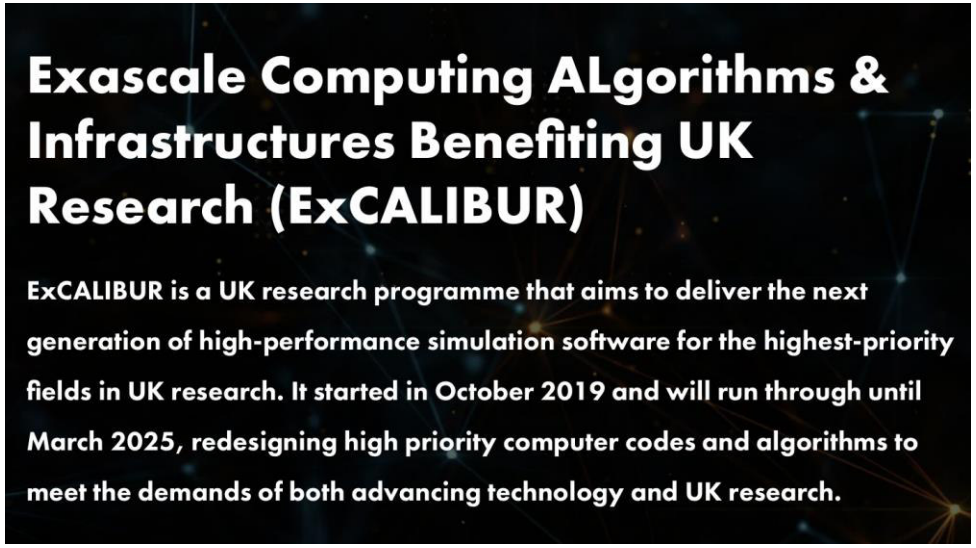
Lack of competitiveness in market conditions

Lack of skills set. Or framing of problem? Or size and structure of data? Or Access to Infrastructure?



https://www.archer2.ac.uk, https://excalibur.ac.uk

New business models to sustain infrastructure

European Cooperative Society (SCE)

A European Cooperative Society (SCE) is an optional legal form of a cooperative. It aims to facilitate cooperatives' cross-border and trans-national activities. The members of an SCE cannot all be based in one country. The SCE is required to unite residents from more than one EU country.

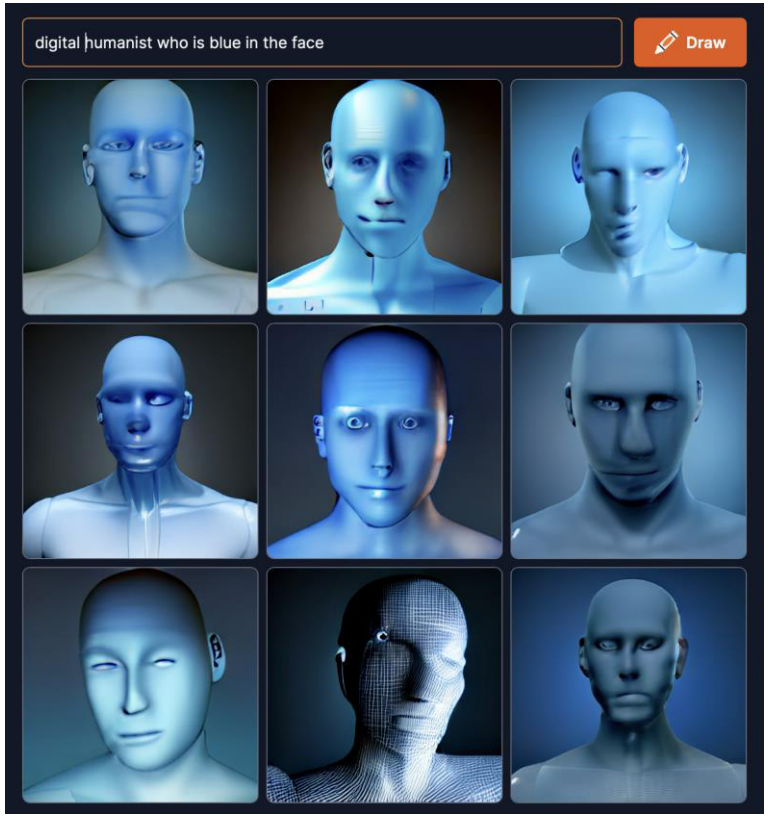
What the SCE is

- a legal entity that allows its members to carry out common activities, while preserving their independence
- its principal object is to satisfy its members' needs and not the return of capital investment
- members benefit proportionally to their profit and not to their capital contribution.

https://single-market-economy.ec.europa.eu/sectors/proximity-and-social-economy/social-economy-eu/cooperatives/european-cooperative-society-sce_en

Do Humanists just need more digital training? Sigh and repeat.

- Upskilling
- Upskilling of management/boards
- Different needs for onboarding to infrastructures
- Prioritisation of interdisciplinary work
- Means to work in teams
- Lobby for the importance of our worldview(s)
- Lobby for what we can *contribute*



Because (Digital) Humanists can contribute

- Ethical approaches
- Understanding Biases
- Power Dynamics
- History of Cultures, Society
- Languages, Literatures
- Psychology
- Communications
- Legal frameworks
- UX/ Transparency
- We need ambition…

Creating the world's first Scottish Gaelic Speech Recognition system

EFI Home / Creating the world's first Scottish Gaelic Speech Recognition system

Researchers are strengthening Scottish Gaelic resources – using automatic speech and handwriting recognition to advance Gaelic language technology

EFI supports interdisciplinary and data-driven research which focusses on navigating an increasingly complex future. Lying at the intersection between ethnography, linguistics and data-driven innovation, Dr Will Lamb and his team are creating and refining the world's first Scottish Gaelic Speech Recognition System.

Automatic Speech Recognition

Automatic Speech Recognition (ASR) technology can be used to translate spoken language into written text. It is used for many purposes in the lives of majority language speakers, for example in subtitling, voice assistant software and dictation services. For minority languages however, these services are often unavailable or inaccurate.

ASR and minority languages

ASR technology needs to be 'trained' with real language input to become more accurate. ASR systems analyse spoken language data, for example, audio recordings from native speakers, and learn about its patterns and structures. The more natural language data there is available, the more accurate the ASR technology can become.

For majority languages such as English there is a wealth of 'real world' language data available, for example, from literature, television, news and radio. This data can be used for training an increasingly accurate ASR system. But for minority languages such as Scottish Gaelic there is usually less of this data available. This means that ASR systems for minority languages struggle to reach the high levels of accuracy that are possible for majority languages.

Digital Approaches to the Capture and Analysis of Watermarks

Project title: Digital approaches to the capture and analysis of watermarks using the manuscripts of Isaac Newton as a test case
Funder: AHRC
Scheme: NEH/AHRC New Directions for Digital Scholarship in Cultural Institutions
UK PI: Scott Mandelbrote, University of Cambridge
Collaborating institutions: Cambridge Digital Humanities
Dates: February 2021–August 2023

This project uses innovative imaging techniques and computer vision to provide an idea of the organisation and chronology of a body of manuscript material (taking the papers of Isaac Newton (1642-1727) as its sample). The dispersal of Newton material through the saleroom in the twentieth century has made accurate comparison of the physical evidence extremely difficult, generating a puzzle in terms of the historical order of the collection. The project is a collaboration between the University of Cambridge, the National Archives, and King's College, Cambridge in the UK and Indiana University, the Huntington Library, and the Science History Institute in the USA, and is funded jointly by the AHRC and the NEH under their call for 'New Directions for Digital Scholarship in Cultural Institutions'. We are building on expertise created at the École des Chartes and by the École des Ponts Paris Tech.

The background to the project is provided by the history of work on Isaac Newton's papers. The Newton Project began an electronic edition of the manuscripts of Isaac Newton in 1998. The Chymistry of Isaac
